CCR SURFACE IMPOUNDMENT

HISTORY OF CONSTRUCTION

Report Issued: September 29, 2016
Revision 0

HARD HAT SERVICES™
Engineering, Construction and Management Solutions

EXECUTIVE SUMMARY

This History of Construction (Report) is prepared in accordance with the requirements of the United States Environmental Protection Agency (USEPA) published Final Rule for Hazardous and Solid Waste Management System – Disposal of Coal Combustion Residual (CCR) from Electric Utilities (40 CFR Parts 257 and 261, also known as the CCR Rule) published on April 17, 2015 and effective October 19, 2015.

This Report documents the construction history of each CCR unit at the Ottumwa Generating Station in Ottumwa, Iowa in accordance with §257.73(c) of the CCR Rule. For purposes of this Report, the term "CCR unit" refers to existing and inactive CCR surface impoundments.

Primarily, this Report is focused on providing history of construction information for each CCR surface impoundment to the extent feasible, provided that such information is reasonably and readily available.

Table of Contents

Figures

Appendices

1 INTRODUCTION

The owner/operator of the CCR units must provide a history of construction for the existing and inactive CCR surface impoundments at the Ottumwa Generating Station (OGS) in Ottumwa, Iowa in accordance with §257.73(c)(1) of the CCR Rule. Hard Hat Services, on behalf of Interstate Power and Light Company, has provided history of construction information for the CCR surface impoundments to the extent feasible, provided that such information is reasonably and readily available.

1.1 CCR Rule Applicability

The CCR Rule requires that an owner/operator of a CCR unit must provide a history of construction for CCR surface impoundments with a height of 5 feet or more and a storage volume of 20 acre-feet or more (§257.73(b)(1)); or for CCR surface impoundments with a height of 20 feet or more (§257.73(b)(2)).

1.2 History of Construction Applicability

OGS has one existing CCR surface impoundment and one inactive CCR surface impoundment, which meet the requirements of §257.73(b)(1) and/or §257.73(b)(2), identified as follows:

- Existing CCR surface impoundment: OGS Ash Pond
- Inactive CCR surface impoundment: OGS Zero Liquid Discharge Pond

2 FACILITY DESCRIPTION

The following sub-sections provide a general facility description.

2.1 Name and Address - §257.73(c)(1)(i)

Included below is the name and address of the owner/operator of the CCR units, name of each CCR unit, and state identification numbers for each CCR Unit (if one has been assigned by the state).

Owner/Operator Name and Address:

Interstate Power and Light Company (*an Alliant Energy Company*)
Ottumwa Generating Station
20775 Power Plant Road
Ottumwa, IA 52501

The names of the CCR Units located at OGS are identified as follows:

- Existing CCR surface impoundment: OGS Ash Pond
- Inactive CCR surface impoundment: OGS Zero Liquid Discharge Pond

The state identification numbers that have been assigned to the CCR Units at OGS, by the Iowa Department of Natural Resources (DNR), are as follows:

- OGS Ash Pond: 90-UDP-01-15
- OGS Zero Liquid Discharge Pond: 90-UDP-01-15

2.2 General Facility History

OGS is located northwest of the City of Ottumwa on the western shore of the Des Moines River in Wapello County. Figure 1 provides both a topographic map and an aerial photograph of the OGS facility location, with the approximate property boundary of the facility identified.

OGS, originally owned/operated by the Iowa Southern Utilities Company and Iowa Electric, initiated construction of the generating plant in 1977. OGS initiated facility operations in 1981. At the time of initial facility operations OGS was a fossil–fueled electric generating station that consisted of one steam electric generating unit (Unit 1).

The initial steam electric generating unit at OGS had a nameplate rating of 675 Megawatts (MW). At the time of initial operations Unit 1 burned coal as its primary fuel source. The coal was transported to and received by the facility via rail car.

The original CCR surface impoundments at OGS were constructed between 1977 and 1981 at the same time as the generating plant. The CCR surface impoundments were initially identified within historical drawings as Ash Pond 1 (presently the OGS Ash Pond) and Ash Pond 2 (presently the OGS Zero Liquid Discharge Pond, also identified as the OGS ZLD Pond). The two CCR surface impoundments were separated by an embankment that consisted of the facility's coal railway spur. The Ash Pond 1 was located to the east of the generating plant and south of the coal railway spur embankment while the Ash Pond 2 was located to the northeast of the generating plant and north of the coal railway spur embankment. Historical drawings that identify the layout of the original CCR surface impoundments are provided in Appendix A. Additional discussions on the construction of the original CCR surface impoundments, as well as modifications to the CCR surface impoundments, are provided in further detail throughout Section 3.

Unit 1 at OGS was constructed with a tangential fired boiler for burning coal. The CCR that was produced from the burning of coal included bottom ash, economizer ash, and precipitator fly ash. The bottom ash that was produced was hydraulically conveyed (sluiced) to the Ash Pond 1 via pipes within an ash trench located between the north end of the generating plant and the northwest corner of the CCR surface impoundment. The bottom ash originally discharged into the northwest corner of the Ash Pond 1. The economizer ash that was produced was collected in an economizer hopper prior to being sluiced to the Ash Pond 1 via the same ash trench as the sluiced bottom ash. The economizer ash, similar to the bottom ash, originally discharged into the northwest corner of the Ash Pond 1. The fly ash that was produced was carried as particulate matter by the flue gases into the electrostatic precipitators, which were installed at the time of initial facility operations. The fly ash would be electrostatically precipitated, collected,

and pneumatically conveyed to a fly ash storage silo. The fly ash that was collected within the fly ash storage silo would be loaded into over-the-road haul trucks and either transported off-site for beneficial reuse or stockpiled along the west side of the Ash Pond 2. Additional discussions on historical operations and handling of the CCR at OGS is provided in further detail throughout Section 3.

In addition to the sluiced CCR, the Ash Pond 1 was also a primary receiver of process water flows from the generating plant. As identified in a Wastewater Reclaim Discharge and Treatment Report[1] dated September 1976, the process water flows that originally discharged into the Ash Pond 1 included flows from an oil separation basin (inclusive of miscellaneous plant floor drains, flash evaporator blowdown, sodium softener regeneration waste, condensate polisher regeneration waste), an ash water pit (inclusive of steam cycle blowdown), cooling tower blowdown, boiler blowdown, sluiced pyrites from the pyrites hopper, activated sludge sanitary wastewater treatment system, as well as other miscellaneous flows. In addition to the process water flows, the Ash Pond 1 was capable of receiving influent flow from the Ash Pond 2 via two 48-inch diameter reinforced concrete pipes (RCPs) located within the embankment that separated the two CCR surface impoundments (See Appendix A). The water within the Ash Pond 2, if high enough in elevation, would overflow into the two 48-inch diameter RCPs and flow to the southwest approximately 88 feet where it would discharge into the northern portion of the Ash Pond 1. The Ash Pond 1 was also a receiver of storm water runoff from the surrounding embankments, as well as storm water collected by the generating plant roof drains and drains located around the generating plant yard.

The process water flows, storm water drainage, and CCR sluice water that accumulated in the Ash Pond 1 flowed to the east and discharged through the facility's National Pollutant Discharge Elimination System (NPDES) Outfall 001 located in the northeast corner of the CCR surface impoundment. The original hydraulic structure consisted of a

[1] Wastewater Reclaim Discharge and Treatment Report, Iowa Southern Utilities Company, Ottumwa Generating Station, September 23, 1976, Black & Veatch Consulting Engineers

14 feet deep cast-in-place concrete structure, a Parshall flume for monitoring flow, and two 66-inch diameter RCPs. The water within the Ash Pond 1 would flow into the concrete structure, through the Parshall flume, and into the two 66-inch diameter RCPs. The water would then flow to the east approximately 180 feet through the two RCPs and discharge into an unnamed creek. The unnamed creek flows into the Des Moines River downstream of the water intake structure and before the confluence of Middle Avery Creek.

The Ash Pond 2, also referred to as a fly ash basin in historical documents, was utilized for storing dry fly ash along the west side of the CCR surface impoundment. The dry fly ash that was not transported off-site for beneficial reuse was stored within the footprint of the Ash Pond 2. Aside from storing dry fly ash, the Ash Pond 2 was used to collect storm water runoff from the dry fly ash, as well as storm water runoff from the surrounding embankments. Additionally, the Ash Pond 2 was capable of receiving influent flow from the Ash Pond 1. Discussions with facility personnel with knowledge of historical operations at OGS confirmed that water within the Ash Pond 1 could be routed into Ash Pond 2 via a hydraulic structure with a control valve. The hydraulic structure was stated to be located within the northwest corner of the Ash Pond 1. The size of the hydraulic structure is not known. The Ash Pond 2 didn't have an outfall discharge structure and therefore the water within the pond either exfiltrated into the ground or evaporated. If the water elevation within the Ash Pond 2 was high enough it had the capability of draining into the Ash Pond 1 via the two 48-inch diameter RCPs. Additional discussions on the historical operation and use of the Ash Pond 2 is provided in further detail in Section 3.

In 1991, the Iowa Southern Utilities Company merged with Iowa Electric to create IES Industries. In 1998, a three-way merger was completed between IES Industries, Interstate Power Company, and Wisconsin Power and Light Company forming Interstate Energy Corporation. In 1999, Interstate Energy Corporation changed its name to Alliant Energy Corporation. Presently, the ownership of OGS includes Mid American Energy and

Interstate Power and Light Company. Interstate Power and Light Company operates the facility.

As OGS exists today, the generating plant consists of one steam electric generating unit. The original generating unit was upgraded in 2014 from 675 MW capacity to 725 MW capacity. Sub-bituminous coal remains the primary fuel for producing steam. The burning of coal at OGS produces three types of CCR, which include bottom ash, economizer ash, and precipitator fly ash. Current CCR operations at OGS include bottom ash and economizer ash being sluiced to the western half of the OGS Ash Pond (formerly identified as the Ash Pond 1). The fly ash produced at OGS is collected by the electrostatic precipitators and pneumatically conveyed to the on-site fly ash storage silo or an on-site fly ash storage building. The fly ash produced is transported off-site via over-the-road haul trucks for beneficial reuse. The OGS ZLD Pond is no longer a primary receiver of CCR or process water flows. Presently, the OGS ZLD Pond acts as a storm water detention pond with the only influent sources being precipitation and storm water runoff from the adjacent hydrated fly ash pile, emergency overflow from the coal pile runoff pond via a 24-inch high density polyethylene (HDPE) pipe, and storm water runoff from the surrounding embankments. The water within the OGS ZLD Pond either exfiltrates into the ground or evaporates. In addition, the Air Quality Control System (AQCS), which consists of a dry scrubber and baghouse, produces scrubber byproducts. The scrubber byproduct is a CCR that is loaded into over-the-road haul trucks and transported to an off-site permitted landfill for disposal. Additional information on the current operations of the two CCR surface impoundments are discussed in further detail throughout Section 3.

3 HISTORY OF CONSTRUCTION - §257.73(c)(1)

This Report documents the history of construction information for each existing and inactive CCR surface impoundment to the extent feasible, provided that such information is reasonably and readily available. The following activities were completed in order to reasonably collect and assemble the readily available history of construction information:

- File review at the local regulatory agency;
- Historical aerial photography review;
- Historical topography review;
- Onsite design drawing, specification, and report review;
- Electronic design drawing, specification, and report review; and
- Interview(s) with onsite personnel with historical knowledge of the existing and inactive CCR surface impoundments.

3.1 OGS Ash Pond

The following subsections are intended to meet the requirements of the CCR Rule §257.73(c)(1) for the OGS Ash Pond.

3.1.1 CCR Unit Location - §257.73(c)(1)(ii)

The OGS Ash Pond is located east of the generating plant on the eastern portion of the site. The location of the OGS Ash Pond, in reference to the surrounding topography, is identified on both a USGS 7 ½ minute topographic quadrangle map and aerial photograph on Figure 1. The location of the OGS Ash Pond, in reference to the immediate surroundings within the OGS property, is identified on Figure 2.

3.1.2 Statement of Purpose - §257.73(c)(1)(iii)

The OGS Ash Pond is the primary receiver of sluiced bottom ash and economizer ash. The CCR is sluiced from the generating plant and discharges into the west side of the OGS Ash Pond. The sluiced CCR is discharged into a collection pad area where the majority of CCR is recovered. A dozer is utilized to scrape the collection pad and push the CCR into a stockpile for dewatering. The stockpile is located within the CCR surface impoundment. The water used to sluice the CCR drains into a narrow treatment channel that flows into the southwest portion of the OGS Ash Pond. Routine maintenance

dredging of the narrow treatment channel occurs as the remaining CCR settles out in the channel.

In addition to sluiced CCR, the OGS Ash Pond is also the primary receiver of process water flows from the generating plant. Current process water flows include boiler blowdown water, solid contact unit (SCU) sludge, water from the oil/water separator, recirculating media sanitary treatment plant, and miscellaneous plant floor drains. Additionally, the OGS Ash Pond receives precipitation and storm water runoff from the surrounding area.

The process water flows, storm water runoff, and CCR sluice water that discharges into the western half of the OGS Ash Pond flows to the northeast towards the facility's NPDES Outfall 001. The water within the OGS Ash Pond flows through a pre-cast concrete mixing channel which then discharges into a small area identified as a polishing pond. The mixing channel provides the ability for chemical addition, if necessary, in order to meet NPDES discharge requirements. The water in the polishing pond discharges through the facility's NPDES Outfall 001. NPDES Outfall 001, similar to its original configuration, consists of a 14 feet deep cast-in-place concrete structure along with a Parshall flume and instrumentation to measure the flow of the discharged water. The water flows into the concrete structure, through the Parshall flume, and through the two 66-inch diameter RCPs. The water then flows to the east approximately 180 feet through the two RCPs and discharges into an unnamed creek. The unnamed creek flows into the Des Moines River downstream of the water intake structure and before the confluence of Middle Avery Creek.

3.1.3 Physical Layout Information - §257.73(c)(1)(iv)

As identified in an Inflow Flood Control Plan[2] prepared for OGS in accordance with §257.82 of the CCR Rule, the OGS Ash Pond has a watershed of approximately 76 acres.

[2] Inflow Flood Control Plan, Ottumwa Generating Station, 2016, Hard Hat Services

The drainage area of the watershed includes 18 acres of level power plant, 18 acres of water surface and embankment, and 40 acres of open low ground.

As discussed in an Annual Inspection Report[3] prepared for OGS in accordance with §257.83 of the CCR Rule, the OGS Ash Pond is incised along the west side of the CCR unit. The north embankment of the OGS Ash Pond separates the CCR surface impoundment from the OGS ZLD Pond. The crest of the north embankment of the OGS Ash Pond consists of the facility's coal railway spur and has an elevation of approximately 681 feet (all elevations provided in feet above mean sea level). The south/east embankment of the OGS Ash Pond has a height of approximately 26 feet from the crest to the toe of the downstream slope of the embankment at its greatest height. The crest of the south/east embankment of the OGS Ash Pond has an elevation of 682 feet. The maximum interior storage depth of the OGS Ash Pond is approximately 25 feet. Currently, the total volume of impounded CCR and water within the OGS Ash Pond is approximately 556,000 cubic yards.

3.1.4 Foundation and Abutment Properties - §257.73(c)(1)(v)

As identified in a Safety Factor Assessment[4] prepared for OGS in accordance with §257.73(e) of the CCR Rule, the embankments of the OGS Ash Pond are constructed of stiff compacted clay from the site overlying the medium stiff native clay which overlies very dense sand of the Des Moines River.

During the construction of OGS in 1974, the native clay was sampled and tested for Atterberg limits, unconfined compressive strength and both consolidated undrained (CU) and unconsolidated undrain (UU) triaxial strength. The test results are shown in Appendix D and indicated that the native clay under the embankments is a low plasticity clay (CL) with unconfined compression values from 1,500 to 2,500 psf. Triaxial UU tests indicated a range of 750 to 2,000 psf for cohesion and the CU tests indicated 29˚ to 34˚ for

[3] Annual Inspection Report, Ottumwa Generating Station, 2016, Hard Hat Services
[4] Safety Factor Assessment, Ottumwa Generating Station, 2016, Hard Hat Services

friction angle and 0 to 600 psf cohesion. The CU test results imply the clay is normally consolidated.

3.1.5 Historical Construction and Use - §257.73(c)(1)(vi)

The OGS Ash Pond (formerly identified as Ash Pond 1 in historical drawings) was constructed between 1977 and 1981 in an area located east of the generating plant. Historical drawings that identify the initial layout of the OGS Ash Pond are provided in Appendix A. Historical aerial photographs that confirm the presence of the OGS Ash Pond at the time of initial facility operations are provided in Appendix B.

There are no known reasonably and readily available documents that detail the method of site preparation and construction of each zone of the OGS Ash Pond. As identified in a General Construction Specification Document[5] dated July 1977, as well as an Ash Pond Slope Stability Report[6] dated October 2010, earthwork specifications for embankments were provided. The specifications stated that to the maximum extent available, suitable earth materials obtained from excavation shall be used for the construction of embankments. Additional material shall be obtained from borrow pits as necessary. The subgrade shall be scarified, leveled, and rolled so that surface materials of the subgrade were compact and well bonded with the first layer of the embankment. All material shall be free from rocks or stones, brush, stumps, logs, roots, debris, and organic or other objectionable materials. Embankments shall be constructed in horizontal layers not exceeding 8 inches in un-compacted thickness. Each layer shall be compacted by rolling or other acceptable methods. The compacted density of each layer shall be at least 95 percent of the maximum density at optimum moisture content as determined by ASTM D698 (or 70 percent of relative density as determined by ASTM D2049).

[5] General Construction (1 of 2) Specification: 6713 C6C, Ottumwa Generating Station, July 1977, Black & Veatch Consulting Engineers

[6] Ash Pond 1 and 2 Slope Stability Report, Interstate Power and Light Ottumwa Power Generating Station, October 22, 2010 Revision 0, Black & Veatch

In-situ soil properties of the CCR unit were identified in a Safety Factor Assessment[7] prepared for OGS in accordance with §257.73(e) of the CCR Rule. As discussed in the Safety Factor Assessment, soil borings were installed in 2016 along the north and south/east embankments of the OGS Ash Pond (See Appendix E). The soil borings installed along the crest of the north embankment and toe of the south/east embankment were completed as part of the CCR surface impoundment monitoring well construction by SCS Engineers. The soil boring installed along the crest of the south/east embankment was completed by Hard Hat Services. Soil samples were collected from the soil boring installed along the crest of the south/east embankment in order to determine water content, Atterberg limits, and grain size (Appendix E). The soil boring data, along with soil sample laboratory analytical results, indicated that the embankments were constructed of stiff compacted clay.

Historical use of the OGS Ash Pond consisted of being the primary receiver of sluiced bottom ash and economizer ash. The bottom ash that was produced was sluiced to the OGS Ash Pond via pipes within an ash trench located between the north end of the generating plant and the northwest corner of the CCR surface impoundment. The bottom ash originally discharged into the northwest corner of the OGS Ash Pond. The economizer ash that was produced was collected in an economizer hopper prior to being sluiced to the OGS Ash Pond via the same ash trench as the sluiced bottom ash. The economizer ash, similar to the bottom ash, originally discharged into the northwest corner of the OGS Ash Pond.

In addition to the sluiced CCR, the OGS Ash Pond was also a primary receiver of process water flows from the generating plant. As identified in a Wastewater Reclaim Discharge and Treatment Report[8] dated September 1976, the process water flows that discharged into the OGS Ash Pond included flows from an oil separation basin (inclusive of

[7] Safety Factor Assessment, Ottumwa Generating Station, 2016, Hard Hat Services
[8] Wastewater Reclaim Discharge and Treatment Report, Iowa Southern Utilities Company, Ottumwa Generating Station, September 23, 1976, Black & Veatch Consulting Engineers

miscellaneous plant floor drains, flash evaporator blowdown, sodium softener regeneration waste, condensate polisher regeneration waste), an ash water pit (inclusive of steam cycle blowdown), cooling tower blowdown, boiler blowdown, sluiced pyrites from the pyrites hopper, as well as other miscellaneous flows. In addition to the process water flows, the OGS Ash Pond was capable of receiving influent flow from the OGS ZLD Pond via two 48-inch diameter RCPs located within the embankment that separates the two CCR surface impoundments (See Appendix A). The water within the OGS ZLD Pond, if high enough in elevation, would overflow into the two 48-inch diameter RCPs and flow to the southwest approximately 88 feet where it would discharge into the northern portion of the OGS Ash Pond. The OGS Ash Pond was also a receiver of storm water runoff from the surrounding embankments, as well as storm water collected by the generating plant roof drains and drains located around the generating plant yard.

The process water flows, storm water drainage, and CCR sluice water that discharged into the OGS Ash Pond flowed to the east and discharged through the facility's NPDES Outfall 001 located in the northeast corner of the CCR surface impoundment. The original hydraulic structure consisted of a 14 feet deep cast-in-place concrete structure, a Parshall flume for monitoring flow, and two 66-inch diameter RCPs. The water within the OGS Ash Pond would flow into the concrete structure, through the Parshall flume, and into the two 66-inch diameter RCPs. The water would then flow to the east approximately 180 feet through the two RCPs and discharge into an unnamed creek. The unnamed creek flows into the Des Moines River downstream of the water intake structure and before the confluence of Middle Avery Creek.

After review of readily available historical documents, there is no readily available information that discusses known modifications to the embankments of the OGS Ash Pond since initial construction of the CCR surface impoundment. The following list provides a general overview of the known modifications associated with the OGS Ash Pond since initial facility operations:

- The Ash Pond 1 was re-identified as the OGS Ash Pond. The timeframe of this modification has not been documented.

- The bottom ash and economizer ash pipes were rerouted from discharging in the northwest corner of the OGS Ash Pond via the ash trench to discharging along the west side of the OGS Ash Pond. The timeframe of this modification has not been documented.

- The two 48-inch diameter RCPs that allowed water from the OGS ZLD Pond to flow into the OGS Ash Pond were permanently sealed. The inlet ends of the two RCPs were sealed with concrete. The timeframe of this modification has not been documented.

- In 2005, an ultrasonic level indicator was installed at NPDES Outfall 001. The ultrasonic level indicator was mounted over the Parshall flume hydraulic structure in order to collect flow data in accordance with the requirements of the facility's NPDES permit for NPDES Outfall 001.

- In 2008, the polishing pond was constructed in the northeast corner of the OGS Ash Pond. The polishing pond, which included the construction of an isolation berm and a pre-cast concrete mixing channel, allowed for the water in the OGS Ash Pond to be routed through a mixing channel prior to discharging through the NPDES Outfall 001. The mixing channel provided OGS the ability to add chemical to the OGS Ash Pond, if necessary, in order to meet NPDES discharge requirements.

Historical aerial photographs (See Appendix B) and historical topographic maps (See Appendix C) identify the topographic changes to the OGS Ash Pond that have occurred since the time of initial facility operations.

3.1.6 Structures, Appurtenances, and Operations- §257.73(c)(1)(vii)

Detailed dimensional drawings of the OGS Ash Pond that were reasonably and readily available are identified below. The detailed dimensional drawings were obtained from various designs, plans, and reports that were assembled during the historical information review.

- Site Work Drawings (1976) – Drawings prepared by Black & Veatch Consulting Engineers provides details of the original design of the OGS Ash Pond at the time of plant construction prior to placement of CCR. Drawings identify original design contours of the OGS Ash Pond, detailed cross-sections of the embankments, and detailed information of the initial hydraulic structure. (Appendix A).

- Field Investigation Soil Borings (1976) – Drawings provide historical soil boring locations and soil boring logs that were completed at OGS in the area of the OGS Ash Pond (Appendix D)

- Process Flow Diagrams (1976) – Figures prepared by Black & Veatch Consulting Engineers provide layout of plant drainage system to the OGS Ash Pond, as well as the bottom ash and economizer ash system to the OGS Ash Pond (Appendix F)

- Effluent Discharge Diagram (1979) – Figure prepared by Iowa Southern Utilities Company provides flow diagram of OGS Ash Pond, OGS ZLD Pond, and coal pile runoff pond (Appendix F).

- Ash Handling System Water Requirements (1984) – Figure provides chart of required flow and required time for flushing of various CCR processes at OGS (Appendix F).

- OGS Water Usage (1995) – Figure provides flow chart of various process flows at OGS (Appendix F).

- OGS Water Usage (2003) – Figure provides flow chart of various process flows at OGS (Appendix F).

- NPDES Outfall 001 Upgrade (2005) – Drawing prepared by Hard Hat Services provides location of new instrumentation to be installed for NPDES Outfall 001 (Appendix F).

- Settling Pond Maintenance Plan (2006) – Drawings prepared by Hard Hat Services provides facility layout, historical settling pond boundaries, and topographic survey with pond volumes (Appendix F).

- Settling Pond Reconfiguration (2007) – Drawings prepared by Hard Hat Services provides modifications to the OGS Ash Pond with the construction of the polishing pond and installation of the mixing channel (Appendix F).

- Monitoring Well Location Map (2016) – Drawing prepared by SCS Engineers provides location of monitoring well installation locations, as well as soil boring logs (Appendix E).

- OGS Ash Pond Soil Borings (2016) – Drawings prepared by Hard Hat Services provides location of soil borings, as well as soil boring logs (Appendix E).

3.1.7 Instrumentation - §257.73(c)(1)(viii)

Instrumentation used to support the operation of the OGS Ash Pond consists of an ultrasonic level indicator mounted over a Parshall flume hydraulic structure in the northeast corner of the OGS Ash Pond. The ultrasonic level indicator was installed in 2005 and replaced the former instrumentation that was used with the hydraulic structure. The ultrasonic level indicator collects flow data in accordance with the requirements of the facility's NPDES permit for NPDES Outfall 001.

3.1.8 Area-Capacity Curve - §257.73(c)(1)(ix)

An area-capacity curve identifies the relationship between the surface area of the existing CCR surface impoundment and an elevation, which corresponds to an available storage capacity. After review of readily available historical documents, there is no readily available information regarding area-capacity curves for the OGS Ash Pond.

3.1.9 Spillway and Diversion Features - §257.73(c)(1)(x)

The OGS Ash Pond is equipped with one hydraulic structure, which is located in the northeast corner of the OGS Ash Pond. The hydraulic structure is identified as NPDES Outfall 001 at OGS. The hydraulic structure consists of a 14 feet deep concrete structure which allows water from the OGS Ash Pond to flow into prior to flowing through a Parshall flume. The water flows through the Parshall flume and into two 66-inch diameter RCPs. The water flows through the two RCPs approximately 180 feet to the east where it discharges into an unnamed creek. The water in the unnamed creek flows to the east where it discharges into the Des Moines River.

3.1.10 Construction Specifications, Surveillance, Maintenance, and Repair - §257.73(c)(1)(xi)

OGS implements a Site-Specific Inspection and Maintenance (I&M) Plan[9], in accordance with an Alliant Energy I&M Plan[10]. The Site-Specific I&M Plan has been implemented at OGS in order to identify the factors which may affect the long-term stability of the existing CCR surface impoundment. The Site-Specific I&M Plan identifies existing operation and maintenance activities, and identifies the inspection, monitoring, maintenance, and recordkeeping requirements as outlined in the Alliant Energy I&M Plan in order to maintain the integrity of the existing CCR surface impoundment.

Visual inspections of the OGS Ash Pond are completed in accordance with §257.83 of the CCR Rule. At intervals not exceeding seven days, the OGS Ash Pond is visually inspected for any appearances of structural weakness or other conditions which are disrupting or have the potential to disrupt the operation or safety of the existing CCR surface

[9] Inspection and Maintenance (I&M) Plan, Ottumwa Generating Station, October 2015, Version 2.0-Revision 0.0
[10] Inspection and Maintenance (I&M) Plan, Alliant Energy, September 2015, Version 2.0-Revision 0.0

impoundment. At intervals not exceeding thirty days, instrumentation serving the OGS Ash Pond is visually inspected to confirm proper working condition. In addition to the seven-day and thirty-day inspections, OGS conducts event-related inspections which may include inspections following storm events, seismic events, major maintenance activities, as well as other unusual events. Annual inspections are conducted by a qualified PE who is familiar with the requirements of the CCR Rule, the Alliant Energy I&M Plan, the OGS Site-Specific I&M Plan, and other facility specific information pertaining to the existing CCR surface impoundment.

Maintenance activities that are completed at OGS may include routine maintenance, event-related maintenance, and long-term maintenance. Routine maintenance activities may include management of vegetation (or other forms of slope protection), tree and sapling removal, reseeding of disturbed vegetated areas, removal of debris from collection and diversion channels, and repair of eroded areas. Event-related maintenance activities may include maintenance after unusual events such as heavy rainfall, periods of very high winds, or seismic activity. Maintenance may include repair of eroded areas or removal of damaged vegetation. Long-term maintenance activities are identified as part of the ongoing inspection program, through the annual inspections, or through other engineering evaluations and may include larger remediation activities.

3.1.11 Structural Instability Records - §257.73(c)(1)(xii)

After review of readily available historical documents there are no known records of structural instability associated with the OGS Ash Pond that were identified.

3.2 OGS Zero Liquid Discharge Pond

The following subsections are intended to meet the requirements of the CCR Rule §257.73(c)(1) for the OGS ZLD Pond.

3.2.1 CCR Unit Location - §257.73(c)(1)(ii)

The OGS ZLD Pond is located northeast of the generating plant and north of the OGS Ash Pond. The location of the OGS ZLD Pond, in reference to the surrounding

topography, is identified on both a USGS 7 ½ minute topographic quadrangle map and aerial photograph on Figure 1. The location of the OGS ZLD Pond, in reference to the immediate surroundings within the OGS property, is identified on Figure 2.

3.2.2 Statement of Purpose - §257.73(c)(1)(iii)

Presently, the OGS ZLD Pond acts as a storm water detention pond with the only influent sources being precipitation and storm water runoff from the surrounding area. The storm water runoff includes the hydrated fly ash pile located along the northwestern side of the CCR surface impoundment, as well as occasional storm water runoff from the coal pile storage area via a 24-inch diameter HDPE pipe located within the north embankment of the OGS ZLD Pond. The OGS ZLD Pond generally operates as a zero liquid discharge pond as the water within the OGS ZLD Pond either exfiltrates into the ground or evaporates.

3.2.3 Physical Layout Information - §257.73(c)(1)(iv)

As identified in an Inflow Flood Control Plan[11] prepared for OGS in accordance with §257.82 of the CCR Rule, the OGS ZLD Pond has a watershed of approximately 44 acres. The OGS ZLD Pond receives storm water from the plant site that was previously used for the production and storing of hydrated fly ash and emergency overflow storm water from the coal pile runoff pond.

The OGZ ZLD Pond is incised along the west side of the CCR unit. The south embankment of the OGS ZLD Pond shares an embankment with the OGS Ash Pond. The crest of the south embankment of the OGS ZLD Pond consists of the facility's coal railway spur and has an elevation of 681 feet. The east embankment of the OGS ZLD Pond also consists of the facility's coal railway spur and has a height of approximately 29 feet from the crest to the toe of the downstream slope of the embankment at its greatest height. The maximum interior storage depth of the OGS ZLD Pond is approximately 25 feet.

[11] Inflow Flood Control Plan, Ottumwa Generating Station, 2016, Hard Hat Services

Currently, the total volume of impounded CCR and water within the OGS ZLD Pond is approximately 515,000 cubic yards.

3.2.4 Foundation and Abutment Properties - §257.73(c)(1)(v)

As identified in a Safety Factor Assessment[12] prepared for OGS in accordance with §257.73(e) of the CCR Rule, the embankments of the OGS ZLD Pond are constructed of stiff compacted clay from the site overlying the medium stiff native clay which overlies very dense sand of the Des Moines River.

During the construction of OGS in 1974, the native clay was sampled and tested for Atterberg limits, unconfined compressive strength and both consolidated undrained (CU) and unconsolidated undrain (UU) triaxial strength. The test results are shown in Appendix D and indicated that the native clay under the embankments is a low plasticity clay (CL) with unconfined compression values from 1,500 to 2,500 psf. Triaxial UU tests indicated a range of 750 to 2,000 psf for cohesion and the CU tests indicated 29˚ to 34˚ for friction angle and 0 to 600 psf cohesion. The CU test results imply the clay is normally consolidated.

In 2016, borings were installed throughout the interior of the OGS ZLD Pond (See Appendix E). The borings within the CCR surface impoundment identified clay beneath the silt or ash sediment layers.

3.2.5 Historical Construction and Use - §257.73(c)(1)(vi)

The OGS ZLD Pond (formerly identified as the Ash Pond 2 in historical drawings) was constructed between 1977 and 1981 in an area located northeast of the generating plant. Historical drawings that identify the initial layout of the OGS ZLD Pond are provided in Appendix A. Historical aerial photographs that confirm the presence of the OGS ZLD Pond at the time of initial facility operations are provided in Appendix B.

[12] Safety Factor Assessment, Ottumwa Generating Station, 2016, Hard Hat Environmental Services

There are no known reasonably and readily available documents that detail the method of site preparation and construction of each zone of the OGS ZLD Pond. As identified in a General Construction Specification Document[13] dated July 1977, as well as an Ash Pond Slope Stability Report[14] dated October 2010, earthwork specifications for embankments were provided. The specifications stated that to the maximum extent available, suitable earth materials obtained from excavation shall be used for the construction of embankments. Additional material shall be obtained from borrow pits as necessary. The subgrade shall be scarified, leveled, and rolled so that surface materials of the subgrade were compact and well bonded with the first layer of the embankment. All material shall be free from rocks or stones, brush, stumps, logs, roots, debris, and organic or other objectionable materials. Embankments shall be constructed in horizontal layers not exceeding 8 inches in un-compacted thickness. Each layer shall be compacted by rolling or other acceptable methods. The compacted density of each layer shall be at least 95 percent of the maximum density at optimum moisture content as determined by ASTM D698 (or 70 percent of relative density as determined by ASTM D2049).

In-situ soil properties of the CCR unit were identified in a Safety Factor Assessment[15] prepared for OGS in accordance with §257.73(e) of the CCR Rule. As discussed in the Safety Factor Assessment, soil borings were installed in 2016 along the south embankment of the OGS ZLD Pond, as well as along the top of the hydrated fly ash pile (See Appendix E). The soil borings installed along the crest of the south embankment were completed as part of the CCR surface impoundment monitoring well construction by SCS Engineers. The soil borings installed along the top of the hydrated fly ash pile were completed by Hard Hat Services. The soil boring data indicated that the embankments were constructed of stiff compacted clay.

[13] General Construction (1 of 2) Specification: 6713 C6C, Ottumwa Generating Station, July 1977, Black & Veatch
[14] Ash Pond 1 and 2 Slope Stability Report, Interstate Power and Light Ottumwa Power Generating Station, October 22, 2010 Revision 0, Black & Veatch Consulting Engineers
[15] Safety Factor Assessment, Ottumwa Generating Station, 2016, Hard Hat Services

Historical use of the OGS ZLD Pond consisted of storing dry fly ash along the west side of the CCR surface impoundment. The dry fly ash that was not transported off-site for beneficial reuse was stored within the footprint of the OGS ZLD Pond. Aside from storing dry fly ash, the OGS ZLD Pond was used to collect storm water runoff from the dry fly ash, as well as storm water runoff from the surrounding embankments. Additionally, the OGS ZLD Pond was capable of receiving influent flow from the OGS Ash Pond. Discussions with facility personnel with knowledge of historical operations at OGS confirmed that water within the OGS Ash Pond could be routed into the OGS ZLD Pond via underground piping which could be isolated with a control valve. The piping was stated to be located within the northwest corner of the OGS Ash Pond. The size of the piping is not known. The OGS ZLD Pond didn't have an outfall discharge structure and therefore the water within the pond either exfiltrated into the ground or evaporated. If the water elevation within the OGS ZLD Pond was high enough it had the capability of draining into the OGS Ash Pond.

After review of readily available historical documents, there is no readily available information that discusses known modifications to the embankments of the OGS Ash Pond since initial construction of the CCR surface impoundment. The following list provides a general overview of the known modifications associated with the OGS ZLD Pond since initial facility operations:

- The Ash Pond 2 was re-identified as the OGS ZLD Pond. The timeframe of this modification has not been documented.

- The two 48-inch diameter RCPs that connected the OGS ZLD Pond to the OGS Ash Pond were permanently sealed. The inlet ends of the two RCPs were sealed with concrete. The timeframe of this modification has not been documented.

- Additional use of the OGS ZLD Pond included receiving runoff from the existing hydrated fly ash pile located along the northwestern side of the CCR surface

impoundment. The hydrated fly ash pile consists of an aggregate-like material produced from Class C fly ash that has been hydrated and hardened. Fly ash, when not transported off-site, was previously hauled from the generating plant to the OGS ZLD Pond where it was hydrated, hardened, and eventually reclaimed for beneficial reuse. The timeframe of this modification has not been documented, however, as of 2015 hydrated fly ash is no longer produced at OGS and the remainder of the existing hydrated fly ash pile is in the process of being reclaimed for beneficial reuse. The hydrated fly ash pile is not located within the current footprint of the OGS ZLD Pond and is not considered to be part of the inactive CCR surface impoundment.

- A 24-inch diameter HDPE emergency overflow pipe was installed in the north embankment of the OGS ZLD Pond. The hydraulic structure was installed in order to allow water within the coal pile runoff pond to overflow into the OGS ZLD Pond, if necessary, in order to control the water elevation within the coal pile runoff pond. The timeframe of this modification has not been documented.

Historical aerial photographs (See Appendix B) and historical topographic maps (See Appendix C) identify the topographic changes to the OGS ZLD Pond that have occurred since the time of initial facility operations.

3.2.6 Structures, Appurtenances, and Operations- §257.73(c)(1)(vii)

Detailed dimensional drawings of the OGS ZLD Pond that were reasonably and readily available are identified below. The detailed dimensional drawings were obtained from various designs, plans, and reports that were assembled during the historical information review.

- Site Work Drawings (1976) – Drawings prepared by Black & Veatch Consulting Engineers provides details of the original design of the OGS ZLD Pond at the time of plant construction prior to placement of CCR. Drawings identify original

design contours of the OGS ZLD Pond, as well as detailed cross-sections of the embankments. (Appendix A).

- Field Investigation Soil Borings (1976) – Drawings provide historical soil boring locations and soil boring logs that were completed at OGS in the area of the OGS ZLD Pond (Appendix D)

- Process Flow Diagrams (1976) – Figures prepared by Black & Veatch Consulting Engineers provide layout of plant drainage system to the OGS ZLD Pond (Appendix F)

- Effluent Discharge Diagram (1979) – Figure prepared by Iowa Southern Utilities Company provides flow diagram of OGS Ash Pond, OGS ZLD Pond, and coal pile runoff pond (Appendix F).

- OGS Water Usage (1995) – Figure provides flow chart of various process flows at OGS (Appendix F).

- OGS Water Usage (2003) – Figure provides flow chart of various process flows at OGS (Appendix F).

- Fly Ash Storage Building (2006) – Drawing prepared by Garden & Associates identifies location of the fly ash storage building constructed at OGS west of the generating plant (Appendix F).

- Settling Pond Maintenance Plan (2006) – Drawings prepared by Hard Hat Services provides facility layout and topographic survey with pond volumes (Appendix F).

- OGS ZLD Pond Bathymetric Survey (2015) – Drawing prepared by Hard Hat Services provides a bathymetric surface of the OGS ZLD Pond (Appendix F)

- Monitoring Well Location Map (2016) – Drawing prepared by SCS Engineers provides location of monitoring well installation locations, as well as soil boring logs (Appendix E).

- OGS ZLD Pond Borings (2016) – Drawings prepared by Hard Hat Services provides location of borings, as well as boring logs (Appendix E).

3.2.7 Instrumentation - §257.73(c)(1)(viii)

The OGS ZLD Pond does not have existing instrumentation that supports the operation of the CCR unit. Additionally, review of readily available historical documents has not identified any past instrumentation that was used to support the operation of the OGS ZLD Pond.

3.2.8 Area-Capacity Curve - §257.73(c)(1)(ix)

An area-capacity curve identifies the relationship between the surface area of the existing CCR surface impoundment and an elevation, which corresponds to an available storage capacity. After review of readily available historical documents, there is no readily available information regarding area-capacity curves for the OGS ZLD Pond.

3.2.9 Spillway and Diversion Features - §257.73(c)(1)(x)

The OGS ZLD Pond does not discharge through any permitted outfall and thus the water within the CCR surface impoundment either exfiltrates into the ground or evaporates. Two 48-inch diameter RCPs, located along the south embankment, previously allowed water to flow from the OGS ZLD Pond into the OGS Ash Pond prior to being permanently sealed with concrete.

3.2.10 Construction Specifications, Surveillance, Maintenance, and Repair - §257.73(c)(1)(xi)

OGS implements a Site-Specific Inspection and Maintenance (I&M) Plan[16], in accordance with an Alliant Energy I&M Plan[17]. The Site-Specific I&M Plan has been implemented at OGS in order to identify the factors which may affect the long-term stability of the

[16] Inspection and Maintenance (I&M) Plan, Ottumwa Generating Station, October 2015, Version 2.0-Revision 0.0
[17] Inspection and Maintenance (I&M) Plan, Alliant Energy, September 2015, Version 2.0-Revision 0.0

existing CCR surface impoundment. The Site-Specific I&M Plan identifies existing operation and maintenance activities, and identifies the inspection, monitoring, maintenance, and recordkeeping requirements as outlined in the Alliant Energy I&M Plan in order to maintain the integrity of the existing CCR surface impoundment.

OGS conducts event-related inspections which may include inspections following storm events, seismic events, major maintenance activities, as well as other unusual events. Visual inspections at intervals not exceeding seven days will be initiated in accordance with amendments to §257.83 of the CCR Rule (i.e., the Extension Rule). Annual inspections are conducted by a qualified PE who is familiar with the requirements of the CCR Rule, the Alliant Energy I&M Plan, the OGS Site-Specific I&M Plan, and other facility specific information pertaining to the existing CCR surface impoundment.

Maintenance activities that are completed at OGS may include routine maintenance, event-related maintenance, and long-term maintenance. Routine maintenance activities may include management of vegetation (or other forms of slope protection), tree and sapling removal, reseeding of disturbed vegetated areas, removal of debris from collection and diversion channels, and repair of eroded areas. Event-related maintenance activities may include maintenance after unusual events such as heavy rainfall, periods of very high winds, or seismic activity. Maintenance may include repair of eroded areas or removal of damaged vegetation. Long-term maintenance activities are identified as part of the ongoing inspection program, through the annual inspections, or through other engineering evaluations and may include larger remediation activities.

3.2.11 Structural Instability Records - §257.73(c)(1)(xii)

After review of readily available historical documents, there are no known records of structural instability associated with the OGS ZLD Pond that were identified.

4 CHANGES TO THE HISTORY OF CONSTRUCTION

If there is a significant change to any information compiled within the Report, the owner or operator of the CCR unit must update the relevant information and place into the facility's operating record as required by §257.105(f)(g).

EDR Aerial Photo Decade Package

Environmental Data Resources, Inc. (EDR) Aerial Photo Decade Package is a screening tool designed to assist environmental professionals in evaluating potential liability on a target property resulting from past activities. EDR's professional researchers provide digitally reproduced historical aerial photographs, and when available, provide one photo per decade.

When delivered electronically by EDR, the aerial photo images included with this report are for ONE TIME USE ONLY. Further reproduction of these aerial photo images is prohibited without permission from EDR. For more information contact your EDR Account Executive.

Thank you for your business.
Please contact EDR at 1-800-352-0050
with any questions or comments.

EDR Topographic Map Library has been searched by EDR and maps covering the target property location as provided by Environmental Site Assessors were identified for the years listed below. EDR's Historical Topo Map Report is designed to assist professionals in evaluating potential liability on a target property resulting from past activities. EDRs Historical Topo Map Report includes a search of a collection of public and private color historical topographic maps, dating back to the late 1800s.

Search Results:

APPENDIX C

LABORATORY TESTING PROGRAM

Discussion of Laboratory Investigation

The split spoon samples were inspected and classified in accordance with the Unified Classification System and the field boring logs were edited as necessary. To aid in classifying the soils and to determine general soil characteristics, natural moisture and density determinations, Atterberg limits tests and sieve analyses were performed on selected samples. The organic contents of some samples were estimated from loss-on-ignition tests.

The undisturbed Shelby tube samples were extruded from the tubes, classified, and natural moistures and densities determined. Atterberg limits tests were performed on selected Shelby tube samples. In order to determine compressibility characteristics, twelve consolidation tests were performed on samples selected to be critical based on probable locations of structures and the results of field and laboratory tests. The conventional load increment ratio of two was employed throughout each test.

To provide undrained shear strength estimates, unconfined compression tests and unconsolidated-undrained triaxial tests were performed on some of the undisturbed samples. Consolidated-undrained triaxial tests (with pore pressure measurements) were performed to determine effective strength parameters. All consolidated-undrained triaxial samples were saturated prior to consolidation.

Compaction tests (according to both ASTM D-698 and ASTM D-1557) were performed on selected bag samples taken from potential on-site borrow areas. Strength and permeability tests were conducted on recompacted samples.

Unconfined compression tests were performed on certain of the rock core samples. Abrasion, soundness and chemical tests were conducted on some of the limestone samples from the eastern portion of the site.

The results of all tests are included in the remainder of Appendix C and Appendices D, E, F, G, H and I.

Table C-4 SUMMARY OF TESTS ON LIMESTONE

1. Test for Determining the Soundness of Coarse Aggregate by Freezing and Thawing
(ISHC Test Method No 211-Method A)

Sample: Boring No 15, 24.2 to 26.4 ft depth
Boring No 15, 29.9 to 31.9 ft depth
Boring No 15, 31.9 to 39.6 ft depth
Boring No 16, 31.0 to 32.4 ft depth
Boring No 16, 32.4 to 36.0 ft depth
Boring No 17, 24.3 to 29.3 ft depth
Boring No 22, 25.6 to 30.3 ft depth

Results: Loss - 16.8%

2. Resistance to Abrasion of Coarse Aggregate by use of the Los Angeles Machine (AASHTO T 96)

Sample: (Same as above)

Results: Loss - 27.8%

3. Analysis of Limestone (ASTM C 25)

Sample: Boring No 15, 31.9 to 40.0 ft depth

Results:

Insoluble matter	1.29%
Total neutralizing value in terms of Ca CO_3	98.25%
Calcium Carbonate (Ca CO_3)	97.00%
Magnesium Carbonate (Mg CO_3)	1.25%

Discussion of Field Investigation

Test borings were made at a total of 52 locations at the site. These locations are indicated on the Plan of Borings (see Figure 2, Appendix A). The borings were extended to depths of from 13.1 to 100 ft. A Mobile B-50 drill rig mounted on an all-terrain type vehicle was used for the field drilling. Hollow stem augers were used for drilling in soil.

Split spoon samples were obtained by the standard penetration test procedure (ASTM D-1586) at 2.5 to 5.0 ft intervals. Representative portions of all samples were sealed in glass jars and returned to our laboratory for inspection and testing. Relatively undisturbed samples were obtained of certain clayey soils by hydraulically pressing 3-in. O.D. Shelby tubes into the soil at selected locations. These samples were obtained in auxiliary borings drilled within a few feet of the original split spoon borings. The tubes were sealed to prevent moisture loss and returned to our laboratory for testing.

The underlying rock was cored at 44 of the 52 boring locations. The depth of rock cored varied from 5.0 to 65.9 ft. All cores were saved and returned to our laboratory in wooden core boxes.

One inch diameter PVC pipe piezometers were installed at ten locations. The lower 18 inches of each pipe was perforated and the bottom capped. Sand was placed in each hole from a depth of at least 3 to 6 inches below the pipe to at least 6 inches above the perforated section. Cement-sand grout was used to backfill the hole above the sand. Piezometer locations were marked by driving steel angle fence posts in a triangular pattern around the pipe at the ground surface. The depths at which the bottom of the pipes were placed are shown on the boring logs.

Logs of all borings have been included on the following pages. The logs show visual descriptions of all soil and rock strata encountered using the Unified Soil Classification System. Ground water observations, sampling information and other pertinent field data are also included. A sheet defining the terms and symbols used on the logs and explaining the standard penetration test procedure is included at the end of this Appendix.

DESCRIPTION

GRAVEL; white; fine to coarse; well graded; moist; trace to some silt.

Silty CLAY; brown mottled w/ gray; non-plastic to low plasticity; moist; trace sand, gravel, coal bits and bottom ash.

@7.5' brown grades out, coal and bottom ash also grade out.

@16' grades dark gray

@28.5' grades trace organic plant matter.

LIMESTONE;white to light gray; weathered.

Bottom of boring at 31'. Boring backfilled w/ soil cuttings to ground surface on 4/28/16.

SCALE IN FEET

NOTES:

1. CONTRACTOR SHALL NOT DISTURB ANY OPERATIONS AT THE FACILITY DURING THE CONSTRUCTION OF THE ISOLATION BERM

2. ISOLATION BERM CONSTRUCTION SEQUENCE:
   1) CONTRACTOR SHALL CONSTRUCT ISOLATION BERM AS SHOWN AND CONSTRUCT A 20 FOOT LONG TEMPORARY SPILLWAY TO ELEVATION 675.85(JOEL SHOW ALIGNMENT AND COORDINATES FOR THE TEMPORARY SPILLWAY AND THE MIXING CHANNEL).
   2) CONTRACTOR SHALL CONSTRUCT THE TEMPORARY DAM TO ELEVATION 678.50 WITH IOWA DOT SPEC. 4120.04 OR 4120.05 STONE.
   3) CONTRACTOR SHALL LOWER THE OUTFALL DISCHARGE TO ELEVATION 673.50
   4) CONTRACTOR SHALL REMOVE STONE AND COMPACT THE SUBGRADE AND INSTALL THE MIXING CHANNEL TO THE DESIGN ELEVATIONS.
   5) AFTER THE CONCRETE MIXING CHANNEL IS SET IN PLACE, THE CONTRACTOR SHALL REMOVE EXCESS STONE MATERIAL FROM THE TEMPORARY DAM TO ESTABLISH THE FINAL GRADES.
   6) CONTRACTOR SHALL REMOVE THE TEMPORARY SPILLWAY BY COMPLETING THE ISOLATION BERM AS SHOWN ON DETAIL XXX.

NOTE:

1. PRECAST CONCRETE COMPRESSIVE STRENGTH SHALL BE MONOLITHIC POUR. TYPE III HIGH-EARLY CONCRETE (4,000 PSI AT 7 DAYS: 6,000 PSI AT 28 DAYS). WITH 5% AIR ENTRAINMENT AND BRUSHED FINISH. CONCRETE CONSTRUCTION SHALL BE IN ACCORDANCE WITH ACI 301-99 AND ACI 318-02. CHANNEL WALLS AND BAFFLE BLOCKS SHALL HAVE CHAMFERED EDGES.
2. THE LIFTING ANGLE FOR THE STRAPS SHALL BE GREATER THAN 45 DEGREES FROM HORIZONTAL.

History of Construction

ALLIANT ENERGY
INTERSTATE POWER AND LIGHT CO.

OTTUMWA GENERATION STATION

GENERAL CONSTRUCTION (1 OF 2)

SPECIFICATION: 6713 C6C
WORK ORDER NO: 81-61-0588-09

BLACK & VEATCH

Section 2A - EARTHWORK

2A.1 GENERAL. This section covers general earthwork and shall include the necessary preparation of the construction areas; removal and disposal of all debris; excavation and trenching as required; the handling, storage, transportation, and disposal of all excavated material; all necessary sheeting, shoring, and protection work; preparation of subgrades; pumping and dewatering as necessary or required; protection of adjacent construction; backfilling; pipe embedment; construction of fills and embankments; surfacing and grading; and other appurtenant work.

2A.2 SHEETING AND SHORING. The stability of previously constructed structures and facilities shall not be impaired or endangered by excavation work. Previously constructed structures and facilities include both structures and facilities existing when this construction began and structures and facilities already provided under these specifications.

Hazardous and dangerous conditions shall be prevented and the safety of personnel shall be maintained. Adequate sheeting and shoring shall be provided as required to protect and maintain the stability of previously constructed structures and facilities and the sides of excavations and trenches until they are backfilled. Sheeting, bracing, and shoring shall be designed and built to withstand all loads that might be caused by earth movement or pressure, and shall be rigid, maintaining shape and position under all circumstances.

2A.3 REMOVAL OF WATER. The Contractor shall provide and maintain adequate dewatering equipment to remove and dispose of all surface and ground water entering excavations and other parts of the work. Each excavation shall be kept dry during subgrade preparation and continually thereafter until the construction to be provided therein is completed to the extent that no damage from hydrostatic pressure, flotation, or other cause will result. Ground water level shall be maintained at least 12 inches below the bottom of each excavation.

2A.4 BLASTING. No blasting or other use of explosives for excavation will be permitted, unless authorized in writing by the Engineer or the Company.

In the event blasting is authorized, the Contractor shall comply with all laws, ordinances, applicable safety code requirements, and regulations relative to the handling, storage, and use of explosives and the protection of life and property. The Contractor shall be responsible for all damage caused by his blasting operations. Suitable methods shall be employed to confine all materials lifted by blasting within the limits of the excavation or trench.

2A.5 CLASSIFICATION OF EARTH MATERIALS. No classification of excavated materials will be made except for identification purposes. Excavation work shall include the removal and subsequent handling of all materials excavated or otherwise removed in performance of the contract work, re gardless of the type, character, composition, or condition thereof.

All rock which cannot be handled and compacted as earth shall be kept separate from other excavated materials and shall not be mixed with backfill, fill, or embankment materials except as specified or directed.

Soil identification shall be in accordance with Table 1 of the Unified Soil Classification System which is bound herewith at the end of this section. Identification and classification shall be based upon visual examination and simple manual tests performed by qualified personnel furnished by the Contractor.

2A.6 FREEZING WEATHER RESTRICTIONS. Backfilling and construction of fills and embankments during freezing weather shall not be done except by permission of the Field Project Manager. No earth material shall be placed on frozen surfaces, nor shall frozen materials, snow, or ice be placed in any backfill, fill, or embankment.

2A.7 MAINTENANCE OF TRAFFIC. The Contractor shall conduct his work so as to interfere as little as possible with the Company's operations and the work of other contractors. Whenever it is necessary to cross, obstruct, or close roads, driveways, parking areas, and walks, the Contractor shall provide and maintain suitable and safe bridges, detours, or other temporary expedients at his own expense. In making open cut road crossings, the Contractor shall not block more than one-half of the road at any time.

Where required, the Contractor shall widen the shoulder on the opposite side of the road to facilitate traffic flow while blocking half of a road with an open cut. Temporary crushed rock surfacing shall be provided as necessary on the widened shoulders.

2A.8 PROTECTION OF UNDERGROUND CONSTRUCTION. The Contractor shall locate, protect, shore, brace, support, and maintain all existing underground pipes, conduits, drains, and other underground construction which may be uncovered or otherwise be affected by the work.

2A.9 PRESERVATION OF TREES. Trees shall be preserved and protected as much as possible. Unless specifically authorized by the Company, trees shall be removed from only those areas which will be excavated, filled, or built upon. Consideration will be given to the removal of additional trees only where essential, in the opinion of the Field Project Manager, for the safe, effective execution of the work.

Trees left standing shall be adequately protected from permanent damage by construction operations. Trimming of standing trees, where required, shall be as directed by the Field Project Manager.

2A.10 UNAUTHORIZED EXCAVATION. Except where otherwise authorized, indicated, or specified, all material excavated below the bottom of concrete structures which will be supported by the subgrade shall be replaced with concrete placed monolithic with the concrete above. Material excavated below structures supported on piers shall be replaced with crushed rock or gravel. The crushed rock or gravel shall be compacted to a density equal to or greater than the density of the adjacent undisturbed soil.

2A.11 STABILIZATION. Subgrades for structures and the bottom of trenches shall be firm, dense, and thoroughly compacted and consolidated; shall be free from mud and muck; and shall be sufficiently stable to remain firm and intact under the feet of the workmen.

Subgrades for structures and trench bottoms which are otherwise solid but which become mucky on top due to construction operations, shall be reinforced with one or more layers of crushed rock or gravel.

The finished elevation of stabilized structure subgrades shall not be above the subgrade elevations indicated on the drawings.

Not more than 1/2 inch depth of mud or muck shall be allowed to remain on stabilized trench bottoms when the pipe embedment material is placed thereon.

All stabilization work shall be performed by and at the expense of the Contractor.

2A.12 TESTING. All field and laboratory testing required to determine compliance with the compaction requirements of this section will be provided by the Company. The Contractor shall provide the services of one or more employees as necessary to assist the Company's field testing representative. The Contractor will be furnished one copy of the test results.

Maximum density for cohesive compacted materials placed under this section will be determined in accordance with ASTM D698. The terms "maximum density" and "optimum moisture content" shall be as defined in ASTM D698.

Relative density for noncohesive compacted materials placed under this section will be determined in accordance with ASTM D2049. The term "relative density" shall be as defined in ASTM D2049.

2A.13 SITE PREPARATION. Ground surfaces within the construction areas will be cleared of all trees and brush under Specification 6713-C-6A, Sitework Construction, and will be essentially free of debris and surface vegetation.

Any remaining brush, trash, and surface vegetation shall be removed in preparing the work site under these specifications and shall be transported to the Company's disposal facility. Waste shall be unloaded and disposed of as directed by the Field Project Manager.

Day-to-day construction waste shall be disposed of as specified in the Special Conditions.

2A.14 ROADWAY ROADBEDS. Roadway roadbed construction shall include excavation and subgrade preparation, and fills and embankments where required. Fills and embankments shall be constructed as specified hereinafter. In excavated roadbed areas, overburden shall be removed and the subgrade shall be shaped to line, grade and cross section, and compacted to a depth of at least 6 inches to 95 per cent of maximum density at optimum moisture content as determined by ASTM D698 when that test is appropriate, or to 70 per cent relative density as determined by ASTM D2049 when that test is appropriate. This operation shall include any scarifying, reshaping, and wetting required to obtain proper compaction. Soft, organic, and otherwise unsuitable material shall be removed from the subgrade and replaced with suitable material.

All material in the upper 18 inches of the subgrade in both cut and fill sections, shall be material with compaction characteristics equal to or better than inorganic clays of low to medium plasticity. This material shall be classified as Group CL or ML as indicated on the Unified Soil Classification chart bound herein at the end of this section.

The subgrade shall be compacted and finished to a true surface and no depression shall be left that will hold water or prevent proper drainage. The subgrade shall be finished to within 0.1 of a foot of the elevation indicated on the drawings. Any deviation of the subgrade surface in excess of one inch as indicated by a 16 foot straightedge, or template cut to typical section, shall be corrected by loosening, adding or removing material, reshaping, and recompacting.

Ditches and drains along the subgrade shall be maintained as required for effective drainage. Whenever ruts of 2 inches or more in depth are formed, the subgrade shall be brought to grade, reshaped, and recompacted. Storage or stockpiling of materials on the subgrade will not be permitted.

Roadway subgrades shall be maintained throughout the work under these specifications.

Roadway surfacing is covered in Sections 2F and 2G of these specifications.

2A.15 FILLS AND EMBANKMENTS. To the maximum extent available, suitable earth materials obtained from excavation shall be used for the construction of fills and embankments. Additional material shall be obtained from borrow pits as necessary. After preparation of the fill or embankment site, the subgrade shall be scarified, leveled, and rolled so that surface materials of the subgrade will be compact and well bonded with the first layer of the fill or embankment. All material deposited in fills and embankments shall be free from rocks or stones, brush, stumps, logs, roots, debris and organic or other objectionable materials. Fills and embankments shall be constructed in horizontal layers not exceeding 8 inches in uncompacted thickness. Material deposited in piles or windrows by excavating and hauling equipment shall be spread and leveled prior to compaction.

Each layer shall be thoroughly compacted by rolling or other methods acceptable to the Engineer. The compacted density of each layer shall be at least 95 per cent of the maximum density at optimum moisture content as determined by ASTM D698 when that test is appropriate or 70 per cent of relative density as determined by ASTM D2049 when that test is appropriate. If the material fails to meet the density specified, compaction methods shall be modified as required to attain the specified density.

2A.15.1 Subgrade Preparation. After preparation of the fill or embankment site, the subgrade shall be leveled and rolled so surface materials of the subgrade will be as compact and well bonded with the first layer of the fill or embankment as specified for subsequent layers.

2A.15.2 Placement and Compaction. All fill and embankment materials shall be placed in approximately horizontal layers not to exceed 8 inches in uncompacted thickness. Material deposited in piles or windrows by excavating and hauling equipment shall be spread and leveled before compaction.

Each layer of material being compacted shall have the best practicable uniform moisture content to insure satisfactory compaction. The Contractor shall add water and harrow, disc, blade, or otherwise work the material in each layer as required to insure uniform moisture content and adequate compaction.

2A.15.3 Borrow Areas. Material necessary to complete fills and embankments shall be excavated from borrow areas and hauled to the fill or embankment site. Borrow material will be available on the Company's property.

The location, size, shape, depth, drainage, and surfacing of all borrow areas shall be acceptable to the Field Project Manager. Borrow areas

shall be regular in shape, with finish graded surfaces when completed. Side slopes shall not be steeper than three horizontal to one vertical, and shall be uniform for the entire length of any one side.

2A.16 STRUCTURE EXCAVATION. Excavation for structures shall be done to lines and elevations indicated on the drawings and to the limits required to perform the construction work. Machine excavation shall be controlled to prevent undercutting the proper subgrade elevations and shall not be used within 10 feet of permanent structures and facilities. Only hand tools shall be used for excavation around permanent structures and facilities.

Work shall be done so that the construction areas will be as free as possible from obstructions and from interference with the transportation, storage, or handling of materials. Excavated materials free of trash, rocks, roots, and other foreign materials, and which meet the specified requirements, may be used as required for the fills, embankments, and backfills constructed under these specifications.

Vertical faces of excavations shall not be undercut to provide for extended footings.

2A.17 STRUCTURE BACKFILL. Backfill around and outside of structures shall be deposited in layers not to exceed 6 inches in uncompacted thickness and mechanically compacted, using platform type tampers, to at least 95 per cent of maximum density at optimum moisture content as determined by ASTM D698 when that test is appropriate, or to 70 per cent relative density as determined by ASTM D2049 when that test is appropriate. at least the density of adjacent undisturbed earth. Compaction of structure backfill by rolling will be permitted provided the desired compaction is obtained and damage to the structure is prevented. Compaction of structure backfill by inundation with water will not be permitted.

Material for structure backfill shall be composed of earth only and shall contain no wood, grass, roots, broken concrete, stones, trash, or debris of any kind.

No tamped, rolled, or otherwise mechanically compacted backfill shall be deposited or compacted in water.

All backfill material shall consist of loose earth having a moisture content such that the required density of the compacted soil will be obtained with the compaction method used. Moisture content shall be distributed uniformly and water for correction of moisture content shall be added sufficiently in advance so that proper moisture distribution and compaction will be obtained. Granular material shall be wet, not just damp, when compacted.

Particular care shall be taken to compact structure backfill which will be beneath pipes, drives, roads, or other surface construction or structures. In addition, wherever a trench will pass through structure backfill, the structure backfill shall be placed and compacted to an elevation at least 12 inches above the top of the pipe before the trench is excavated.

2A.18 COMPACTED ROCK FILL. Compacted rock fill shall consist of crushed rock conforming to ASTM C33, gradation 1-1/2 inch to crusher fines. The rock fill shall be placed on undisturbed subgrade and compacted to maximum density. Compaction shall be performed with vibrating mechanical compactors unless otherwise acceptable to the Engineer.

Compacted rock fill shall be placed under all slabs 24 inches or less in thickness. The thickness of the compacted rock fill shall be a minimum of 6 inches.

Crushed rock for compacted fill shall be handled and placed in a manner that will prevent segregation of sizes. The fill material shall have the best practicable moisture content to achieve maximum density with the compaction methods used. The material shall be placed in horizontal layers not more than 6 inches in uncompacted thickness.

If concrete is to be placed on the compacted rock fill, the fill shall be finished with a thin layer of clean concrete sand to fill all voids and interstices and to obtain the required subgrade elevation. A polyethylene film moisture barrier shall be placed over the sand as specified in the cast-in-place concrete section.

2A.19 MAINTENANCE AND RESTORATION OF FILLS, EMBANKMENTS, AND BACKFILLS. Fills, embankments and backfills that settle or erode before final acceptance of the work under these specifications, and pavement, structures, and other facilities damaged by such settlement or erosion, shall be repaired. The settled or eroded areas shall be refilled, compacted, and graded to conform to the elevation indicated on the drawings or to the elevation of the adjacent ground surface. Damaged facilities shall be repaired in a manner acceptable to the Field Project Manager.

Earth slopes of the roads constructed under these specifications shall be maintained to the lines and grades indicated on the drawings until the final acceptance of the road slopes by the Field Project Manager.

2A.20 FINAL GRADING. After all construction work under these specifications has been completed, all ground surface areas disturbed by this construction or construction plant and operations shall be graded. The grading shall be finished to the contours and elevations indicated on the drawings or, if not indicated, to the matching contours and elevations of the original, undisturbed ground surface. In any event, the final grading shall provide smooth uniform surfacing and effective drainage of the ground areas.

2A.21 DISPOSITION OF MATERIALS. Excavated earth material shall be used to construct fills, embankments and backfills to the extent required. Surplus earth, if any, and materials which are not suitable for fills, embankments, and backfills shall be spoiled on the site in a manner and location as directed by the Field Project Manager.

Materials shall be deposited in the disposal areas and leveled and compacted in 12 inch maximum layers. Compaction shall be by not less than three passes of a bulldozer.
